### Comparison with the RKF45 Method

Numerical Analysis (Chapter 5)

#### Comparison with the RKF45 Method

 The Runge-Kutta-Fehlberg method is used for error control because at each step it provides, at little additional cost, two approximations that can be compared and related to the local truncation error.

→ ∃ →

#### Comparison with the RKF45 Method

- The Runge-Kutta-Fehlberg method is used for error control because at each step it provides, at little additional cost, two approximations that can be compared and related to the local truncation error.
- Predictor-corrector techniques always generate two approximations at each step, so they are natural candidates for error-control adaptation.

★ ∃ →

#### Comparison with the RKF45 Method

- The Runge-Kutta-Fehlberg method is used for error control because at each step it provides, at little additional cost, two approximations that can be compared and related to the local truncation error.
- Predictor-corrector techniques always generate two approximations at each step, so they are natural candidates for error-control adaptation.
- To demonstrate the error-control procedure, we construct a variable step-size predictor-corrector method using the 4-step explicit Adams-Bashforth method as predictor and the 3-step implicit Adams-Moulton method as corrector.

### 4-step Explicit Adams-Bashforth Method

The Adams-Bashforth 4-step method comes from the relation

$$y(t_{i+1}) = y(t_i) + \frac{h}{24} [55f(t_i, y(t_i)) - 59f(t_{i-1}, y(t_{i-1})) + 37f(t_{i-2}, y(t_{i-2})) - 9f(t_{i-3}, y(t_{i-3}))] + \frac{251}{720} y^{(5)}(\hat{\mu}_i) h^5$$

for some  $\hat{\mu}_i \in (t_{i-3}, t_{i+1})$ .

< ロ > < 同 > < 回 > < 回 >

### 4-step Explicit Adams-Bashforth Method

The Adams-Bashforth 4-step method comes from the relation

$$\begin{aligned} y(t_{i+1}) &= y(t_i) + \frac{h}{24} [55f(t_i, y(t_i)) - 59f(t_{i-1}, y(t_{i-1})) \\ &+ 37f(t_{i-2}, y(t_{i-2})) - 9f(t_{i-3}, y(t_{i-3}))] + \frac{251}{720} y^{(5)}(\hat{\mu}_i) h^5 \end{aligned}$$

for some  $\hat{\mu}_i \in (t_{i-3}, t_{i+1})$ . The assumption that the approximations  $w_0, w_1, \ldots, w_i$  are all exact implies that the Adams-Bashforth local truncation error (LTE) is

$$\frac{y(t_{i+1}) - w_{i+1}^{\rho}}{h} = \frac{251}{720} y^{(5)}(\hat{\mu}_i) h^4$$

### 3-Step Implicit Adams-Moulton Method

A similar analysis of the Adams-Moulton method which comes from

$$y(t_{i+1}) = y(t_i) + \frac{h}{24} [9f(t_{i+1}, y(t_{i+1})) + 19f(t_i, y(t_i)) - 5f(t_{i-1}, y(t_{i-1})) + f(t_{i-2}, y(t_{i-2}))] - \frac{19}{720} y^{(5)}(\tilde{\mu}_i) h^5$$

for some  $\tilde{\mu}_i \in (t_{i-2}, t_{i+1})$ ,

э

### 3-Step Implicit Adams-Moulton Method

A similar analysis of the Adams-Moulton method which comes from

$$\begin{aligned} y(t_{i+1}) &= y(t_i) + \frac{h}{24} [9f(t_{i+1}, y(t_{i+1})) + 19f(t_i, y(t_i)) - 5f(t_{i-1}, y(t_{i-1})) \\ &+ f(t_{i-2}, y(t_{i-2}))] - \frac{19}{720} y^{(5)}(\tilde{\mu}_i) h^5 \end{aligned}$$

for some  $\tilde{\mu}_i \in (t_{i-2}, t_{i+1})$ , leads to the local truncation error (LTE):

$$rac{y(t_{i+1})-w^c_{i+1}}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^4$$

where  $w_{i+1}^c$  represents the corrected approximation given by the 3-Step implicit Adams-Moulton method.

#### **Crucial Assumption**

To proceed further, we must make the assumption that for small values of *h*, we have

$$\gamma^{(5)}(\hat{\mu}_i) pprox \pmb{y}^{(5)}(\tilde{\mu}_i)$$

The effectiveness of the error-control technique depends directly on this assumption.

### Combining the LTE Estimates

If we subtract the AB4 (predictor) local truncation error estimate

$$\frac{y(t_{i+1}) - w_{i+1}^{p}}{h} = \frac{251}{720}y^{(5)}(\hat{\mu}_{i})h^{4}$$

・ロト ・ 一 ト ・ ヨ ト ・ ヨ ト

### Combining the LTE Estimates

If we subtract the AB4 (predictor) local truncation error estimate

$$\frac{y(t_{i+1}) - w_{i+1}^{\rho}}{h} = \frac{251}{720}y^{(5)}(\hat{\mu}_i)h^4$$

from the AM4 (corrector) local truncation error estimate

$$rac{y(t_{i+1})-w^c_{i+1}}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^2$$

Numerical Analysis (Chapter 5)

10/33

### Combining the LTE Estimates

If we subtract the AB4 (predictor) local truncation error estimate

$$\frac{y(t_{i+1}) - w_{i+1}^{\rho}}{h} = \frac{251}{720}y^{(5)}(\hat{\mu}_i)h^4$$

from the AM4 (corrector) local truncation error estimate

$$rac{y(t_{i+1})-w_{i+1}^c}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^4$$

we have

$$rac{w_{i+1}^c-w_{i+1}^
ho}{h}=rac{h^4}{720}[251y^{(5)}(\hat{\mu_i})+19y^{(5)}( ilde{\mu_i})]pproxrac{3}{8}h^4y^{(5)}( ilde{\mu_i})$$

・ロト ・ 一 ト ・ ヨ ト ・ ヨ ト

э

$$\frac{w_{i+1}^c - w_{i+1}^\rho}{h} = \frac{h^4}{720} [251y^{(5)}(\hat{\mu_i}) + 19y^{(5)}(\tilde{\mu_i})] \approx \frac{3}{8}h^4y^{(5)}(\tilde{\mu_i})$$

### Combining the LTE Estimates (Cont'd)

Therefore

$$y^{(5)}( ilde{\mu}_i) pprox rac{8}{3h^5}(w^c_{i+1} - w^p_{i+1})$$

$$\frac{w_{i+1}^c - w_{i+1}^\rho}{h} = \frac{h^4}{720} [251y^{(5)}(\hat{\mu_i}) + 19y^{(5)}(\tilde{\mu_i})] \approx \frac{3}{8}h^4y^{(5)}(\tilde{\mu_i})$$

### Combining the LTE Estimates (Cont'd)

Therefore

$$y^{(5)}(\tilde{\mu}_i) \approx \frac{8}{3h^5}(w^c_{i+1} - w^p_{i+1})$$

Using this result to eliminate the term involving  $y^{(5)}(\tilde{\mu}_i)h^4$  in

$$rac{y(t_{i+1})-w^c_{i+1}}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^4$$

gives the following approximation to the Adams-Moulton local truncation error:

Numerical Analysis (Chapter 5)

11/33

### Combining the LTE Estimates (Cont'd)

The approximation to the Adams-Moulton local truncation error is finally:

$$|\tau_{i+1}(h)| = \frac{|y(t_{i+1}) - w_{i+1}^c|}{h}$$

### Combining the LTE Estimates (Cont'd)

The approximation to the Adams-Moulton local truncation error is finally:

$$|v_{i+1}(h)| = rac{|y(t_{i+1}) - w_{i+1}^c|}{h}$$
  
 $pprox rac{19h^4}{720} \cdot rac{8}{3h^5} |w_{i+1}^c - w_{i+1}^p|$ 

 $|\tau|$ 

# LTE of the Predictor-Corrector Method

### Combining the LTE Estimates (Cont'd)

The approximation to the Adams-Moulton local truncation error is finally:

$$|w_{i+1}(h)| = rac{|y(t_{i+1}) - w_{i+1}^c|}{h}$$
  
 $\approx rac{19h^4}{720} \cdot rac{8}{3h^5} |w_{i+1}^c - w_{i+1}^p|$   
 $= rac{19}{270h} |w_{i+1}^c - w_{i+1}^p|$

Changing the Step-Size

Numerical Analysis (Chapter 5)

Variable Step-Size Multistep Methods

R L Burden & J D Faires

14/33

### Changing the Step-Size

Suppose we now reconsider the 3-step AM4 Corrector LTE equation

$$\frac{y(t_{i+1}) - w_{i+1}^c}{h} = -\frac{19}{720}y^{(5)}(\tilde{\mu_i})h^4$$

with a new step size qh generating new approximations  $\hat{w}_{i+1}^p$  and  $\hat{w}_{i+1}^c$ .

< ロ > < 同 > < 三 > < 三 >

### Changing the Step-Size

Suppose we now reconsider the 3-step AM4 Corrector LTE equation

$$rac{y(t_{i+1})-w^c_{i+1}}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^4$$

with a new step size *qh* generating new approximations  $\hat{w}_{i+1}^{p}$  and  $\hat{w}_{i+1}^{c}$ .

 The object is to choose *q* so that the local truncation error given in this equation is bounded by a prescribed tolerance *ε*.

14/33

< ロ > < 同 > < 三 > < 三 >

### Changing the Step-Size (Cont'd)

If we assume that the value  $y^{(5)}(\mu)$  in the equation

$$rac{y(t_{i+1})-w^c_{i+1}}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^4$$

associated with qh

### Changing the Step-Size (Cont'd)

If we assume that the value  $y^{(5)}(\mu)$  in the equation

$$rac{y(t_{i+1})-w^c_{i+1}}{h}=-rac{19}{720}y^{(5)}( ilde{\mu_i})h^4$$

associated with qh is also approximated using

$$y^{(5)}(\tilde{\mu_i}) \approx \frac{8}{3h^5}(w^c_{i+1} - w^p_{i+1})$$

## Changing the Step-Size (Cont'd)

If we assume that the value  $y^{(5)}(\mu)$  in the equation

$$rac{y(t_{i+1})-w_{i+1}^c}{h}=-rac{19}{720}y^{(5)}( ilde{\mu}_i)h^4$$

associated with qh is also approximated using

$$y^{(5)}(\tilde{\mu_i}) \approx rac{8}{3h^5}(w^c_{i+1} - w^p_{i+1})$$

$$\frac{\text{then}}{|y(t_i+qh)-\hat{w}_{i+1}^c|} = \frac{19q^4h^4}{720}|y^{(5)}(\mu)| \approx \frac{19q^4h^4}{720}\left[\frac{8}{3h^5}|w_{i+1}^c - w_{i+1}^p|\right]$$

## Changing the Step-Size (Cont'd)

If we assume that the value  $y^{(5)}(\mu)$  in the equation

$$rac{y(t_{i+1})-w_{i+1}^c}{h}=-rac{19}{720}y^{(5)}( ilde{\mu}_i)h^4$$

associated with qh is also approximated using

$$y^{(5)}(\tilde{\mu_i}) \approx \frac{8}{3h^5}(w^c_{i+1} - w^p_{i+1})$$

$$\frac{\frac{19q^4h^4}{|y(t_i+qh)-\hat{w}_{i+1}^c|}}{qh} = \frac{19q^4h^4}{720}|y^{(5)}(\mu)| \approx \frac{19q^4h^4}{720}\left[\frac{8}{3h^5}|w_{i+1}^c - w_{i+1}^p|\right]$$
$$= \frac{19q^4}{270}\frac{|w_{i+1}^c - w_{i+1}^p|}{h}$$

Numerical Analysis (Chapter 5)

### Changing the Step-Size (Cont'd)

We need to choose q so that

$$rac{|y(t_i+qh)-\hat{w}_{i+1}^c|}{qh} pprox rac{19q^4}{270} rac{|w_{i+1}^c-w_{i+1}^p|}{h} < arepsilon$$

16/33
#### Changing the Step-Size (Cont'd)

We need to choose q so that

$$rac{|y(t_i+qh)-\hat{w}_{i+1}^c|}{qh}pprox rac{19q^4}{270}\,rac{|w_{i+1}^c-w_{i+1}^p|}{h}$$

That is, choose q so that

$$q < \left(\frac{270}{19} \frac{h\varepsilon}{|w_{i+1}^{c} - w_{i+1}^{p}|}\right)^{1/4} \approx 2\left(\frac{h\varepsilon}{|w_{i+1}^{c} - w_{i+1}^{p}|}\right)^{1/4}$$

Numerical Analysis (Chapter 5)

Variable Step-Size Multistep Methods

$$q < \left(\frac{270}{19} \frac{h\varepsilon}{\left|w_{i+1}^c - w_{i+1}^p\right|}\right)^{1/4} \approx 2\left(\frac{h\varepsilon}{\left|w_{i+1}^c - w_{i+1}^p\right|}\right)^{1/4}$$

#### Changing the Step-Size (Cont'd)

 A number of approximation assumptions have been made in this development, so in practice q is chosen conservatively, often as

$$q = 1.5 \left(\frac{h\varepsilon}{\left|w_{i+1}^c - w_{i+1}^p\right|}\right)^{1/4}$$

4 A N

#### The Cost of a Change in Step-Size

 A change in step size for a multistep method is more costly in terms of function evaluations than for a one-step method, because new equally-spaced starting values must be computed.

< ロ > < 同 > < 三 > < 三 >

#### The Cost of a Change in Step-Size

- A change in step size for a multistep method is more costly in terms of function evaluations than for a one-step method, because new equally-spaced starting values must be computed.
- As a consequence, it is common practice to ignore the step-size change whenever the local truncation error is between  $\varepsilon/10$  and  $\varepsilon$ , that is, when

$$\frac{\varepsilon}{10} < |\tau_{i+1}(h)| = \frac{|y(t_{i+1}) - w_{i+1}^c|}{h} \approx \frac{19|w_{i+1}^c - w_{i+1}^p|}{270h} < \varepsilon$$

イロン イボン イヨン イヨン

#### The Cost of a Change in Step-Size

- As a consequence, it is common practice to ignore the step-size change whenever the local truncation error is between  $\varepsilon/10$  and  $\varepsilon$ , that is, when

$$\frac{\varepsilon}{10} < |\tau_{i+1}(h)| = \frac{|y(t_{i+1}) - w_{i+1}^c|}{h} \approx \frac{19 \left| w_{i+1}^c - w_{i+1}^p \right|}{270h} < \varepsilon$$

• In addition, *q* is given an upper bound (e.g. 4) to ensure that a single unusually accurate approximation does not result in too large a step size.

#### Step 21 STOP

#### Example: Applying the Algorithm

Use the Adams variable step-size predictor-corrector method with maximum step size hmax = 0.2, minimum step size hmin = 0.01, and tolerance  $TOL = 10^{-5}$  to approximate the solution of the initial-value problem:

$$y' = y - t^2 + 1,$$
  $0 \le t \le 2,$   $y(0) = 0.5$ 

#### Solution (1/5)

Numerical Analysis (Chapter 5)

#### Solution (1/5)

• We begin with h = hmax = 0.2, and obtain  $w_0$ ,  $w_1$ ,  $w_2$  and  $w_3$  using Runge-Kutta, then find  $w_4^p$  and  $w_4^c$  by applying the predictor-corrector method.

(日)

#### Solution (1/5)

- We begin with h = hmax = 0.2, and obtain  $w_0$ ,  $w_1$ ,  $w_2$  and  $w_3$  using Runge-Kutta, then find  $w_4^p$  and  $w_4^c$  by applying the predictor-corrector method.
- These calculations were done in an earlier example where it was determined that the Runge-Kutta approximations are:

$y(0) = w_0$	=	0.5	
$y(0.2) \approx w_1$	=	0.8292933	
$y(0.4) \approx w_2$	=	1.2140762	and
$y(0.6) \approx w_3$	=	1.6489220	

(日)

Solution (2/5)

The predictor and corrector gave

$$y(0) = w_0 = 0.5$$

- $y(0.2) \approx w_1 = 0.8292933$
- $y(0.4) \approx w_2 = 1.2140762$
- $y(0.6) \approx w_3 = 1.6489220$

$$y(0.8) \approx w_4^p = w_3 + \frac{0.2}{24} (55f(0.6, w_3) - 59f(0.4, w_2) + 37f(0.2, w_1))$$

 $-9f(0, w_0))$ 

$$= 2.1272892$$
  
 $y(0.8) \approx w_4^c = w_3 + \frac{0.2}{24} \left(9f(0.8, w_4^p) + 19f(0.6, w_3) - 5f(0.42, w_2) + f(0.2, w_1)\right)$ 

= 2.1272056

#### Solution (3/5)

We now need to determine if these approximations are sufficiently accurate or if there needs to be a change in the step size.

・ 同 ト ・ ヨ ト ・ ヨ

#### Solution (3/5)

We now need to determine if these approximations are sufficiently accurate or if there needs to be a change in the step size. First we find:

$$\delta = \frac{19}{270h} |w_4^c - w_4^p| = \frac{19}{270(0.2)} |2.1272056 - 2.1272892| = 2.941 \times 10^{-5}.$$

・ 同 ト ・ ヨ ト ・ ヨ
#### Solution (3/5)

We now need to determine if these approximations are sufficiently accurate or if there needs to be a change in the step size. First we find:

$$\delta = \frac{19}{270h} |w_4^c - w_4^p| = \frac{19}{270(0.2)} |2.1272056 - 2.1272892| = 2.941 \times 10^{-5}.$$

Because this exceeds the tolerance of  $10^{-5}$ , a new step size is needed and the new step size is:

$$qh = \left(\frac{10^{-5}}{2\delta}\right)^{1/4} = \left(\frac{10^{-5}}{2(2.941 \times 10^{-5})}\right)^{1/4} (0.2) = 0.642(0.2) \approx 0.128.$$
